TITLE: Powder magnesium and magnesium-beryllium alloys

SOURCE: Poroshkovaya metallurgiya, no. 5, 1965, 46-53

TOPIC TAGS: powder magnesium alloy, powder magnesium beryllium alloy, powder magnesium oxide containing alloy, magnesium alloy property

ABSTRACT: Powder magnesium-magnesium oxide alloys containing 0.3 to 10% MgO and super heat-resistant magnesium-beryllium alloys containing 1 to 10% Be have been developed. Magnesium powder MTF-1 (-0.500 to +0.160 mm) and MTF-4 (-0.200 to +0.050 mm; GOST 6001-51) produced by the rapid milling method, and magnesium oxide obtained by surface oxidation of magnesium powder in air at 300-450°C for several hours were used. Magnesium alloys were prepared by cold compacting the powder mixture into bars, 65 x 150 mm, under a pressure of 25-30 kn/cm² for 0.5-1.5 min. The compacted bars were then hot extruded at 500-5200 with 98-99% reduction under a pressure of 0-25 kn/cm². A mixture of oil with laminated graphite was used for lubrication during hot extrusion. Magnesium oxide, even in small amounts, substan-

Card 1/2

tially improved the strength of magnesium alloys, and its effectiveness increased with increasing temperature. However, the addition of 0.3 to 5% magnesium oxide had little effect on the tensile strength at all investigated temperatures. The addition of magnesium oxide also improved the structural stability and mechanical properties of magnesium-beryllium alloys. The addition of beryllium increased resistance to high-temperature oxidation and reduced the sensitivity to overheating. The properties of magnesium-beryllium alloys excelled those of magnesium alloys. Powder magnesium-beryllium alloys have been used for shielding uranium fuel elements in nuclear reactors and have been tested successfully for 6000 hr at temperatures of 500-520°C and a neutron flux of $2 \cdot 10^{20}$ n/cm². TITLE: Method for producing diode matrices. Class 42, No. 177688 [announced by
Institute of Cybernetics, AN UkrSSR (Institut kibernetiki AN UkrSSR)]

SOURCE: Izobreteniya, promyshlennyye obraztsy, tovarnyye znaki, no. 1, 1966, 109

TOPIC TAGS: microelectronic circuit, avalanche diode

ABSTRACT: This Author Certificate presents a method for producing diode matrices, e.g., from microelectronic n-p-n (p-n-p) matrices by feeding the voltage along two mutually perpendicular buses into given cross wires of the matrix. To eliminate isolating sections of the cross wires and for possible bipolar switching of the elements (diodes), the voltage of either polarity is supplied with an amplitude exceeding the avalanche breakdown voltage of the n-p (p-n) junction.

nickel containing tin in comparison with pure nickel at 800°C. Antimony in concentrations up to 0.013% has no significant effect on the breaking strength of nickel in the given temperature range. Lead and bismuth reduce breaking strength at all temperatures with a difference of about 20% at 700°C. The yield stress of the alloys shows little change in comparison with pure nickel at any temperature, although there is a slight increase in σ_s at approximately 300°C both for pure nickel and for the solutions studied. Alloys with maximum admixture concentrations show somewhat of an increase in ductility near 300°C. The given impurities have the greatest effect on nickel properties, particularly ductility, in the high temperature range. The value of δ in the alloys with maximum Pb and Bi concentrations is 15-30% lower than for pure nickel with even more of a reduction at high temperatures. At 700-800°C the difference reaches a factor of 3-4. Similar changes are observed in ψ as a function of temperature and impurity with the exception of tin which increases the ductility of nickel. Only at 700°C is there a slight reduction in δ in comparison with pure nickel. Beyond this point the ductility of the Ni-Sn alloy increases sharply, the values of δ and ψ reaching 3 times those of pure nickel at 800°C. Orig. art. has: 3 figures, 2 tables.

TITLE: Internal friction in powder metal magnesium

SOURCE: AN SSSR. Institut metallurgii. Vnutrennuye treniye v metallakh i splavakh
(Internal friction in metals and alloys). Moscow, Izd-vo Nauka, 1966, 163-166

TOPIC TAGS: internal friction, powder metal, shear modulus, magnesium, vibration measurement

ABSTRACT: Powdered magnesium was oxidized to obtain samples with differing amounts of MgO (0.3, 2.3 and 5% by weight), annealed at 500°C for one hour, and subjected to measurement of change in vibration amplitude in order to determine internal friction (η^{-1}), as well as shear modulus with respect to temperature. There are fairly consistent data on the curves for the three alloys with respect to strength (mechanical) properties, increasing or decreasing, as the case may be, with respect to MgO content. The path of curves for the temperature relationship of internal friction and shear modulus can be explained by dispersion hardening effect found in MgO. Grain boundaries, type of impurities and distribution of impurities in the

Card 1/2

ACC NR: AT6026916

3

alloy also influences the internal friction. For purposes of comparison the relationship of $Q^{-1}(T)$ is presented for technical magnesium MG-1, which had been hot pressed, where it is evident that the height of the peak for $Q^{-1}(T)$ differs little from the peak for MG-1, increasing but slightly for increased MgO content. This may be caused by a structural refinement in alloys containing a large amount of the finely dispersed oxide phase, plus high degrees of distortions and increased numbers of defects in the polycrystalline structure. Orig. art. has: 6 figures.

TITLE: Internal friction in powder metal beryllium

SOURCE: AN SSSR. Institut metallurgii. Vnutrennaya treniya v metallakh i splavakh
(Internal friction in metals and alloys). Moscow, Izd-vo Nauka, 1966, 166-169

TOPIC TAGS: internal friction, powder metal, shear modulus, elastic modulus,
beryllium

ABSTRACT: Previous studies of internal friction for such powder metal systems as
Cu-Fe-Ni, Cu-Mo, Cu-W, Ni + Al₂O₃, SAP and beryllium have shown that the temperature
relationship of internal friction Q-1 (T) affects the nature of the initial components
the method of producing a compact material and its structure. This paper discusses
the same property, plus shear modulus and modulus of elasticity, for hot-pressed
powder metal alloys of Be-BeO containing 0.3, 1.5 and 7% by weight BeO. Testing
was conducted in a vacuum relaxation tester at forced torsion oscillations in re-
sonance. Internal friction was determined according to change of oscillation ampli-
tude along with measurement of frequency for constructing the temperature relation-
ship of shear modulus and modulus of elasticity. Samples were vacuum annealed one

hour at 1,000°C prior to testing to remove stresses and adsorbed gases and to put the alloy in a more equilibrium state. Test results show maximums for all curves, and according to the authors, the behavior of these maximums depends on solubility of the components, their concentration, distribution and other factors. From a comparison of the high-temperature "background" of $Q^{-1}(T)$ it is clear that temperature of abrupt growth of the curve increases with oxide content while slope of curve becomes less. This "background" can serve as a criterion of increasing heat resistance with increased oxide content. Orig. art. has: 3 figures.

TITLE: Time-delay element for contactless transistorized control
systems

SOURCE: Avtomatika i priborostroyeniye, no. 2, 1964, 22-25

TOPIC TAGS: contactless control system, time delay stability, time
delay duration, control system time delay, time delay element

ABSTRACT: Several variants of improved time-delay elements and their basic circuits are described. The first circuit uses a transistorized two-stage amplifier and a diode as the output key. This circuit, together with other contactless logic elements, makes it possible to achieve higher time delays of the control system (as compared with electromechanical relays) without affecting the performance of the system. Because of certain disadvantages a second highly stable time-delay circuit was developed.(see Fig. 1 of the Enclosure). It represents an integrator-amplifier with high amplification using transistors T₂—T₅. Transistor T₁ is a logical NOR circuit. The amplifier

Card 1 / 3

ACCESSION NR: AP4040425

(T_3 and T_4) with capacitive negative feedback (capacitor C_1) is the basic element ensuring time delay. According to experiments, a time delay of 7—10 sec can be achieved with the use of this circuit at an ambient temperature in excess of 46°C. Voltage-supply fluctuations of $\pm 30\%$ produce an error in time delay not exceeding $\pm 0.3\%$. For the case where there is no requirement of high temperature stability, a third variant of the time-delay circuit has been developed. This circuit produces time delays of 10 sec. In the fourth variant described, temperature increases up to 70°C produce a time-delay error not exceeding 5%, while the error caused by voltage fluctuations of $\pm 30\%$ does not exceed 3%. SOURCE: Priborostroyeniye, no. 3, 1965, 17-19

TOPIC TAGS: transistorized power supply, voltage stabilization, electronic equipment

ABSTRACT: A low voltage power source developed at the All-Union Scientific Research Institute of Pipes is described in detail. The device is designed for producing stabilized voltages necessary for working with semiconductor devices. This equipment is able to produce simultaneously: 1) dc voltage regulated within 0.5% and smoothly variable in ranges of 0-35 and 8-25 volts; 2) one of the standard dc voltages regulated with an accuracy of 0.2%, or unregulated alternating voltages of 1, 3, 6, 12 and 24 volts; 3) one of the standard unregulated voltages of 48 and 60 volts, ac and dc. Regulated voltage pulsation does not exceed 2 millivolts; dc output impedance of the regulated sources is no more than 0.17 Ω. All regulated volt-

age outputs may be loaded up to 2 amps, unregulated outputs--up to 5 amps. The electronic portion of the device is completely transistorized. The device has over-load and heat protection. This power supply operates at 10-40°C, humidity should not exceed 90% at 20°C. Total weight--12.4 kg, overall dimensions--500 x 300 x 250 mm. A schematic diagram is given in fig. 1 of the Enclosure. The operating principles are completely described. Orig. art. has: 1 figure.

SOURCE: AN UkrSSR. Poluprovodnikovaya tekhnika i mikroelektronika
(Semiconductor engineering and microelectronics). Kiev, Naukova dumka,
1966, 79-91

TOPIC TAGS: photodiode, semiconductor diode, light modulation

ABSTRACT: Position-sensitive photodiodes have been produced which are based on n-p diffusion junctions in Ge doped with antimony and Si doped with boron. A 4 x 4 mm semiconductor n-p plate was divided into four equal parts by two perpendicular cuts which were deeper than the n-p junction and were 0.1 mm wide. Electrodes were deposited on the surface of each of the four photodiodes to record the output signal. In the Ge photodiodes the density of the reverse saturation current was 1-2 mamp/mm²; photosensitivity of the samples was 20-30 mamp/lm. The figures for Si photodiodes were (2-3)10⁻³ mamp/mm (at 3 v), and

TITLE:

On the Formation of Free Hydrogen in the Earth Crust, Caused by the Reducing Action of Products of Isotope Radioactive Decay (Ob obrazovanii svobodnogo vodoroda v zemnoy kore, obuslovlennom vesstanovitel'nym deystviem produktov radioaktivnogo prevrashcheniya izotopov)

PERIODICAL:

Geokhimiya, 1958, Nr 1, pp. 14-21 (USSR)

ABSTRACT:

Hydrogen is produced by the action of Ca^{40} and Sr^{87} on water. These are the products of the transformation of K^{40} Rb^{87} resp. According to the data of A. A. Cherepennikov (ref. 4) the content of hydrogen and other gases of carnallites and sylvinites of various layers of the mine of Solikamsk is shown. A theoretical computation from the K^{40} - and Rb^{87} -content leads to a similar result; possibilities for explaining the deviation are discussed. Furthermore the gas contents of various samples from the mine of Berezniki are given. As is shown by these analyses, hydrogen is produced only in solving by the action of Ca and Sr on water,

Card 1/2

On the Formation of Free Hydrogen in the Earth Crust, Caused by the Reducing Action of Products of Isotope Radioactive Decay 7-1-2/12

it is therefore not present in elementary shape already before.

The possible gas quantities in rocks which are formed by the transformation of K⁴⁰, Rb⁸⁷, Th²³², U²³⁸ and U²³⁵, have been computed; here the content of helium is theoretically of the same order of magnitude as the hydrogen content.

There are 5 tables and 8 references, all of which are Slavic.

SOV/20-129-3-18/70The Electron Autoemission Images of Crystals of
Orderable Alloys

Several figures show typical electron images recorded immediately after breakdown in the vacuum. The emission of electrons is the same for nearly all parts of the "pimplies". In addition to the roughness of the surface, deep holes in the layers of the "pimplies" occur on the surface. In the figures round, black spots correspond to these holes, which are displaced with the entire figure under the influence of a magnetic field. The homogeneity of the emission and the holes in the surface of the "pimplies" show that the structure of the "pimplies" within the limits of the resolving power of the electron projector is amorphous. Heating the points consisting of Ni_3Mn and AuCu_3 alloys to 40 to 60°, signs of a crystallographical limitation of the "pimplies" occur. The equilibrium images resulting from an intense heating of the alloys Ni_3Mn , AuCu_3 , PtCu_3 and the pure metals Ni and Au indicate that the "pimplies" are well-bounded crystals. For the definite and final determination of the structure of the initial surface the authors intend carrying out investigations by means of an ion projector. In the alloy Ni_3Mn the diffusion

TITLE: Adsorption, Migration and Evaporation of Be Deposited
on W monocrystalPERIODICAL: Radiotekhnika i elektronika, 1960, Vol.5, No.8,
pp.1211-1217

TEXT: The system Be-W is of interest for several reasons. Be is an alkali-earth metal and Be films should reduce the W work function; published measurements of Be work function date back 20 years; and the study of Be on W monocrystal would permit verification of Drechsler's calculations (Ref.7) concerning migration and evaporation of atoms on W monocrystals for the region of small adsorbate atomic radii. A study was accordingly carried out, using a Müller projector (Ref.8). Emission patterns were obtained showing the migration of beryllium over a tungsten monocrystal (Fig.1), the behaviour of thick films (Fig.2) and evaporation (Fig.3). It was found that Be work function is higher than that of W. (Preliminary results give $\varphi_{Be} = 5$ eV). It was further found that the work function of W is either increased or decreased by a beryllium monolayer, in dependence on crystallographic direction.

TITLE: A New Method of Preparing Field Emitters From
Low-melting Point Metals and Alloys

PERIODICAL: Radiotekhnika i elektronika, 1960, Vol. 5,
No. 8, pp. 1342 - 1346

TEXT: Field emitters of Ni_3Mn and similar materials have been prepared by the use of vacuum breakdown in a projector tube between a point of the investigated material (negative electrode) and the screen (positive electrode). A resistive or inductive element is used to restrict the breakdown to a local breakdown. This resulted in the formation of protuberances. A number of field emission patterns obtained in the projector tube are reproduced. There are 3 figures and 7 references: 2 Soviet and 5 non-Soviet.

TITLE: Effect of impurities and dislocations on the auto-emission
of electrons in the case of metallic crystals

PERIODICAL: Fizika tverdogo tela, v. 4, no. 5, 1962, 1346 - 1351

TEXT: Microscopic exposures were made of the emission from technically pure platinum, silver, and copper single crystals. The specimens were heated in a vacuum of $\leq 10^{-3}$ mm Hg, some of them to more than 1000°C, emission being induced by continuous or pulsed voltage of 3 - 40 kv. Iron was sputtered onto a platinum specimen which was then heated to 700°C for a period of 6 min, within which the iron dissolved in the platinum. When the specimen was cooled rapidly, the pictures showed bright spots spreading rapidly over the whole specimen after 1 min heating at 900°C. A small bulge developed at the tip of the specimen as a result of electric discharges. The specimen was then heated to 1200°C and allowed to cool down to room temperature. This caused some

Card 1/2

S/181/62/004/005/040/055

Effect of impurities....

of the white spots to disappear, whilst others darkened preserving a bright fringe. These erupting white spots are the impurities which diffuse rapidly from the cylindrical part toward the tip of the specimen, emerging at the surface along with the dislocations, where the intensity of electron emission is locally damped by them. As a result of this emergence of impurities, a cathode formed of commercial platinum becomes purified through alternate heating and cooling under a high vacuum in the electric force field. There can be no doubt of the correlation found to exist between the appearance of bright spots in the microscopic picture and electric breakdown. If the tip of the specimen is thoroughly purified from impurities and dislocations, breakdown is difficult to achieve, even if a multiple of the voltage is applied which before purification was sufficient to cause it. There are 4 figures and 1 table.

scopy

ABSTRACT: The purpose of the investigation was to obtain quantitative information on the cross sections of the molecular complexes that cause the unusual electron-microscope pictures of tungsten needles on which low-molecular compounds are deposited. The published information on this subject is contradictory, and the observed spots were frequently attributed to separate molecules. Another purpose of the investigation was to check on the "waveguide" theory of

Card 1/3

2

the occurrence of these spots, proposed by one of the authors elsewhere (A. P. Komar and A. A. Komar, ZhTF v. 31, 231, 1961). The actual experiment consisted in finding a way of "landing" some calibration object of known radius $\ll 1 \mu$ on the end of a metal needle with radius $\rho \leq 1 \mu$. By getting around the difficulties of such an experiment, the authors succeeded in checking on the formula given by J. Rose for the local magnification (J. Appl. Phys. v. 27, 215, 1956), making it possible to determine the transverse dimensions of the formations in question from their images on the projector screen. Some 600 spots, in the form of two-petal and four-petal figures, were produced by condensing copper phthalocyanine or anthraquinone from vapor on a tungsten needle cooled with liquid nitrogen. The radius a of the spot was determined with a formula derived from the Rose formula, in which all the quantities could be readily determined. The test procedure is briefly described. The experimentally obtained ratio of the radii of the two-petal and four-petal formations was close to that calculated on the basis of the Rose for-

B

AUTHOR: Komar, A. P.; Savchenko, V. P.

TITLE: "Waveguide" theory of autoelectronic emission of molecular complexes of semiconductors and experimental results

SOURCE: Fizika tverdogo tela, v. 7, no. 3, 1965, 759-768

TOPIC TAGS: autoelectronic emission, electron microscope, polymer filament, semiconductor, waveguide theory

ABSTRACT: Reports are presented of an experimental determination of the ratio of the individual forms of the so-called "molecular" spots produced by anomalous auto-electronic emission of polymer filaments of semiconductor substances. The substances tested were the low-molecular organic semiconductors phthalocyanine, tolane, an-thraquinone, and propargylic acid, the semimetals selenium, tellurium, and graphite, and the metals antimony and bismuth. The dimensions of the filaments were determined by the authors earlier (DAN SSSR v. 158, 131, 1964) and were found to be such as to make waveguide propagation of the electromagnetic waves through these filaments possible. The experimental method is based on a relation established between

Card 1/2

L 49050-65

ACCESSION NR: AP5006878

the wave numbers of the modes that can propagate in a cylindrical waveguide and the autoemission pattern that can be observed with the aid of an electron microscope. The experimental procedure and equipment are described. Spots hitherto unobserved but predicted by the waveguide theory have been observed for the first time, and ordinary spots due to the semimetals selenium, tellurium, and carbon have been noted. The agreement between theory and experiment is considered to be good and confirms that the anomalous autoelectronic emission of adsorbed or condensed organic and inorganic semiconducting materials and metallic points can be satisfactorily described with the aid of the waveguide model for delocalized electrons passing through thin polymer filaments stretched along the lines of the electric field. Orig. art. has: 5 figures and 9 formulas.

TITLE: Effect of an electric field on the behavior, dimensions and form of molecular patterns

SOURCE: Fizika tverdogo tela, v. 8, no. 2, 1966, 457-463

TOPIC TAGS: field emission microscope, molecular pattern, phthalocyanine, organo-copper compound, electric field, aromatic hydrocarbon

ABSTRACT: Data are given from an experimental study of the effect which an electric field has on the shape, dimensions and behavior of molecular patterns on the screen of a field emission microscope produced by vaporization of quaterphenyl and copper phthalocyanine. The results are compared with the conclusions of theories on the origin of molecular patterns. It is found that molecular patterns may be produced in an electron projector by vaporizing an organic substance on the needle

Card 1/2

L 31175-66

ACC NR: AP6006830

in a constant electric field or by holding an adsorbed layer in a constant electric field. The time for formation of the molecular objects responsible for the pattern on the screen is more than 300 μ sec. This indicates that simple adsorption of molecules on the surface of the needle is insufficient for forming molecular patterns. The molecular complexes of copper phthalocyanine formed by a constant electric field retain their structure outside the field and produce molecular patterns even in a pulsed electric field. Only the dimensions of the molecular patterns change with the voltage and not their form. The rate of increase in the dimensions of the molecular patterns with an increase in voltage decreases as the voltage approaches a certain maximum value and in some cases reaches a saturation point. This relationship between dimensions and voltage may be explained by distortion of the equipotential lines of the electric field above the outer end of the molecular complex. The range of voltages in which molecular patterns are possible is 0.2 V_{max} for pairs and 0.15 V_{max} for quadruplets. The range of variations in the dimensions of the molecular patterns is 0.35 W_{max} for pairs and 0.2 W_{max} for quadruplets. Orig. art. has: 6 figures, 2 formulas.

TITLE: Application of invariant theory to automatically controlled ships which use hydrofoils

SOURCE: AN UkrSSR. Slozhnyye sistemy upravleniya X (Complex control systems). Kiev,
Naukova dumka, 1965, 135-145

TOPIC TAGS: hydrofoil, marine engineering, automatic control

ABSTRACT: An important problem in modern marine theory is the use of automatically controlled hydrofoils for assuring dynamic stability in the motion of ships in an agitated medium. A basic difficulty in solution of this problem is the requirement for maximum accuracy in holding the controlled parameters at a predetermined level even when there are extremely irregular variations in the external disturbances. One of the fundamental conditions for a successful solution of the problem of compensating for the effect of external perturbations, or the invariance problem, is that there must be two channels for transmitting the action from the disturbance to the parameter to be controlled. A system of automatically controlled hydrofoils satisfies this requirement for two channels. The present author studies the effect of external perturbations on hydrofoils, starting with a system of differential equations for longitudinal motion of a hydrofoil ship in a quiet medium, in terms of three coordinate systems.

ABSTRACT: This Author Certificate presents equipment for continuous production of ammonites, containing a device for preliminary crushing, drying, and sifting of the components, dosing conveyors with feeders and screw conveyors, a mill-mixer, and a device for sealing the finished product, all interconnected by conveyors. To increase the accuracy of the continuous dosing of components, the dosing conveyors are suspended from one equal arm of a beam balance with shields mounted at the ends. The shields pass a light ray onto the photocell of an automatic device which varies the component feed rate onto the dosing conveyors when the equilibrium between them is disturbed (see Fig. 1 on the Enclosure). Orig. art. has: 1 diagram.

Abstract : Intravenous introduction of histamine (0.15 mg/kg) into rabbits produced an increase in capillary permeability particularly obvious in the control nervous system, liver, kidneys, myocardium. The greatest rise in permeability appeared after 1-2 days and was sustained for 8 days. If the histamine-poisoned rabbits were subject to a general x-ray irradiation of small doses (20 r), then in the majority of animals (19-out of 24) the increased permeability began to decrease after the second irradiation.
